## 0.1 Categories

### Definition 1: Category

A **category**  $\mathcal{C}$  is a class of **objects**  $\text{ob}(\mathcal{C})$  along with sets of **morphisms** between those objects. The set of morphisms  $A$  to  $B$  is denoted  $\text{Hom}_{\mathcal{C}}(A, B)$ . There must be a law of composition of morphisms, i.e. for all objects  $A, B$ , and  $C$ , there is a map

$$\text{Hom}_{\mathcal{C}}(A, B) \times \text{Hom}_{\mathcal{C}}(B, C) \rightarrow \text{Hom}_{\mathcal{C}}(A, C)$$

that sends the pair of morphisms  $(f, g)$  to their composition  $gf$ . Finally, the objects and morphisms satisfy:

1. If  $A \neq C$  or  $B \neq D$ , then  $\text{Hom}_{\mathcal{C}}(A, B)$  and  $\text{Hom}_{\mathcal{C}}(C, D)$  are disjoint sets.
2. Morphism composition is associative.
3. Each object has an identity morphism, i.e. for object  $A$ , there is a map  $1_A \in \text{Hom}_{\mathcal{C}}(A, A)$  such that  $1_A g = g$  and  $f 1_A = f$  for all  $f \in \text{Hom}_{\mathcal{C}}(A, B)$  and  $g \in \text{Hom}_{\mathcal{C}}(B, A)$ , where  $B$  is arbitrary.

We will drop the subscript  $\mathcal{C}$  in  $\text{Hom}_{\mathcal{C}}$  if the category is clear.

### Definition 2: Subcategory

$\mathcal{C}$  is a subcategory of  $\mathcal{D}$  if

1. every object of  $\mathcal{C}$  is an object of  $\mathcal{D}$ ; and
2. for all objects  $A, B$  in  $\mathcal{C}$ ,  $\text{Hom}_{\mathcal{C}}(A, B) \subset \text{Hom}_{\mathcal{D}}(A, B)$ .

**Proposition 1.** *The identity morphism of an object is unique.*

*Proof.* Suppose  $1_A$  and  $1'_A$  are both identity morphisms of  $A$ . Then by the two equalities in condition (3) above,  $1_A = 1_A 1'_A = 1'_A$ .  $\square$

### Definition 3: Endomorphism

An **endomorphism** of  $A$  is a morphism from  $A$  to itself.

#### Definition 4: Isomorphism

An isomorphism  $f : A \rightarrow B$  is an invertible morphism, i.e. there exists a morphism  $g : B \rightarrow A$  such that  $gf = 1_A$  and  $fg = 1_B$ .

**Proposition 2.** *Inverses of morphisms are unique.*

*Proof.* Suppose  $f : A \rightarrow B$  is a morphism and  $g, g' : B \rightarrow A$  are both inverses of it. Then by associativity of morphism composition,  $g = g1_B = g(fg') = (gf)g' = 1_Ag' = g'$ .  $\square$

Now for some examples to make this *somewhat* less abstract.

1. **Set**: the category of all sets. The category of all finite sets is a subcategory of this.
  - $\text{Hom}(A, B)$  is the set of all functions from  $A$  to  $B$ .
  - Morphism composition is the usual composition of functions.
  - The identity morphism sends  $a \in A$  to itself.
2. **Grp**: the category of all groups. **Ab**, the category of all abelian groups, is a subcategory of this. Morphisms are group homomorphisms, and isomorphisms are, well, group isomorphisms.
3. **Ring**: the category of all nonzero rings with 1. The morphisms are ring homomorphisms that send 1 to 1.
4. **R-mod**: the category of all left  $R$ -modules. The morphisms are  $R$ -module homomorphisms.
5. **Top**: the category of all topological spaces. The morphisms are continuous maps between spaces, and the isomorphisms are homeomorphisms.

#### Definition 5: Discrete Category

A **discrete category** is a category in which all the morphisms are identities, i.e. every object is isolated.

#### Definition 6: Opposite/Dual Category

Given a category  $\mathcal{C}$ , its **opposite** or **dual** category  $\mathcal{C}^{\text{op}}$  is the category gotten by reversing the morphisms of  $\mathcal{C}$ . Formally,  $\text{ob}(\mathcal{C}^{\text{op}}) = \text{ob}(\mathcal{C})$ , but

$$\text{Hom}_{\mathcal{C}^{\text{op}}}(A, B) = \text{Hom}_{\mathcal{C}}(B, A).$$

Note that the identities in a category and its dual are the same. Compositions, on the other hand, are reversed.

Figure 1: A category and its dual. Since every object must have an identity morphism, I usually won't include them in a diagram unless necessary.

### Definition 7: Product Category

Given categories  $\mathcal{C}$  and  $\mathcal{D}$ , we can define their **product category**  $\mathcal{C} \times \mathcal{D}$  as having the objects

$$\text{ob}(\mathcal{C} \times \mathcal{D}) = \text{ob}(\mathcal{C}) \times \text{ob}(\mathcal{D})$$

and the morphisms

$$\text{Hom}_{\mathcal{C} \times \mathcal{D}}((A, B), (A', B')) = \text{Hom}_{\mathcal{C}}(A, A') \times \text{Hom}_{\mathcal{D}}(B, B').$$

It is straightforward to define the identity morphisms and the composition of morphisms in product categories in a piecewise fashion, building off the identities and composition laws of  $\mathcal{C}$  and  $\mathcal{D}$ .

## 0.2 Functors

Functors map categories to categories by associating objects with objects and morphisms with morphisms in ways that respect morphism composition and identities.

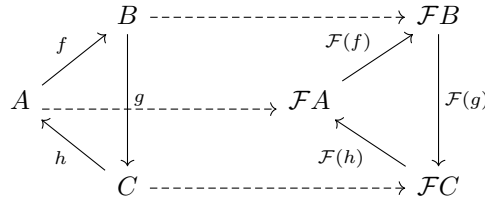

Figure 2: A functor  $\mathcal{F}$  between two categories.

**Definition 8: (Covariant) Functor**

A **(covariant) functor**  $\mathcal{F} : \mathcal{C} \rightarrow \mathcal{D}$  satisfy:

1. For every object  $A$  in  $\mathcal{C}$ ,  $\mathcal{F}A$  is an object in  $\mathcal{D}$ .
2. For every  $f \in \text{Hom}_{\mathcal{C}}(A, B)$ ,  $\mathcal{F}(f)$  is a morphism in  $\text{Hom}_{\mathcal{D}}(\mathcal{F}A, \mathcal{F}B)$  such that
  - (a)  $\mathcal{F}(gf) = \mathcal{F}(g)\mathcal{F}(f)$ , and
  - (b)  $\mathcal{F}(1_A) = 1_{\mathcal{F}A}$ .

**Example 1: Category Inception**

The category **CAT** has objects that are themselves categories, and its morphisms are functors.

**Definition 9: Domain/Codomain**

Given a functor  $f \in \text{Hom}_{\mathcal{C}}(A, B)$ ,  $A$  is the **domain** and  $B$  is the **codomain** of  $f$ .

There are tons of examples of functors, so here are some that aren't too complicated.

1. The **identity functor**  $\mathcal{I}_{\mathcal{C}}$  maps  $\mathcal{C}$  to  $\mathcal{C}$  by sending objects and morphisms to themselves.
2. If  $\mathcal{C}$  is a subcategory of  $\mathcal{D}$ , then the **inclusion functor** maps  $\mathcal{C}$  to  $\mathcal{D}$  by sending objects and morphisms to themselves, except now as members of  $\mathcal{D}$  instead of  $\mathcal{C}$ .
3. **Forgetful functors** take a category and strip its objects of some kind of complexity, i.e. a functor from **Grp** to **Set**. A forgetful functor doesn't have to just map objects to plain sets, though. We could also map **Ab** to **Grp**, forgetting the abelian nature of the groups in our category.

**More examples.**

In order to “respect” morphisms, we might either keep the morphisms all in the same direction or flip them. If we decide to flip them all, we get a different type of functor.

**Definition 10: Contravariant Functor**

A **contravariant functor** from  $\mathcal{C}$  to  $\mathcal{D}$  is a functor from  $\mathcal{C}^{\text{op}}$  to  $\mathcal{D}$ .
